

CRREM-aligned strandingIndicative 1.5°C pathways — not the licensed CRREM dataset

Transition-risk screening using the CRREM **method**: a building's annual operational carbon intensity is compared against a declining 1.5°C decarbonisation pathway, and the first year the (held-flat) intensity exceeds the pathway is its **stranding year**. The pathways here are indicative, 1.5°C-aligned anchors by asset type — **not** the official licensed CRREM curves (which require a CRREM License Partner agreement) and not country-grid specific. Decision-support, not an assured disclosure.

of stranded assets

PER-ASSET ASSESSMENT

BUILDING	INTENSITY	PATHWAY 2026	STRANDING YEAR	STATUS
Berliner Bürogebäude Alpha OFFICE	13.3	43.4	2045	Stranding 2045

Intensity and pathway are in kgCO₂/m²·yr. Intensity is annualised from the latest ~30 days of operational emissions and held flat — a conservative screening view that does not credit planned decarbonisation. Improving efficiency or electrifying heat (see the recommendations) pushes the stranding year out.

METHOD & ASSUMPTIONS

Pathways are linearly interpolated between indicative 2025 and 2050 anchors per asset type (1.5°C-aligned). A building is **stranded now** if its intensity already exceeds the 2025 pathway, **on track** if it stays at or below the 2050 endpoint, otherwise **stranding** in the first year the pathway falls below it. Swapping in the licensed CRREM curves (per type and country grid) is a single-module change once a License Partner agreement is in place.

Prepared using the CRREM methodology with indicative 1.5°C pathways. This is reporting support / transition-risk screening — it is not the official CRREM tool output, not audited or assured, and not investment advice. Confirm against the licensed CRREM dataset before external use.
